

# 32. Common Concurrency Problems.

Operating System: Three Easy Pieces

---

# Common Concurrency Problems

- ▣ More recent work focuses on studying other types of **common concurrency bugs**.
  - ◆ Take a brief look at some example concurrency problems found in real code bases.

# What Types Of Bugs Exist?

- ▣ Focus on four major open-source applications [Lu08]
  - ◆ MySQL, Apache, Mozilla, OpenOffice.

Application	What it does	Non-Deadlock	Deadlock
MySQL	Database Server	14	9
Apache	Web Server	13	4
Mozilla	Web Browser	41	16
Open Office	Office Suite	6	2
<b>Total</b>		<b>74</b>	<b>31</b>

## Concurrency Bugs In Modern Applications

# Non-Deadlock Bugs

- ▣ Make up a majority of concurrency bugs.
- ▣ Two major types of non deadlock bugs:
  - ◆ Atomicity violation
  - ◆ Order violation

# Atomicity-Violation Bugs

- ▣ The desired **serializability** among multiple memory accesses is *violated*.
  - ◆ Simple Example found in MySQL:
    - Two different threads access the field `proc_info` in the struct `thd`.

```
1  Thread1::
2  if(thd->proc_info){
3      ...
4      fputs(thd->proc_info , ...);
5      ...
6  }
7
8  Thread2::
9  thd->proc_info = NULL;
```

# Atomicity-Violation Bugs (Cont.)

- ▣ **Solution:** Simply add locks around the shared-variable references.

```
1  pthread_mutex_t lock = PTHREAD_MUTEX_INITIALIZER;
2
3  Thread1::
4  pthread_mutex_lock(&lock);
5  if(thd->proc_info){
6      ...
7      fputs(thd->proc_info , ...);
8      ...
9  }
10 pthread_mutex_unlock(&lock);
11
12 Thread2::
13 pthread_mutex_lock(&lock);
14 thd->proc_info = NULL;
15 pthread_mutex_unlock(&lock);
```

# Order-Violation Bugs

- The **desired order** between two memory accesses is flipped.
  - ◆ i.e., **A** should always be executed before **B**, but the order is not enforced during execution.
  - ◆ **Example:**
    - The code in Thread2 seems to assume that the variable `mThread` has already been *initialized* (and is not `NULL`).

```
1  Thread1::  
2  void init() {  
3      mThread = PR_CreateThread(mMain, ...);  
4  }  
5  
6  Thread2::  
7  void mMain(...) {  
8      mState = mThread->State  
9  }
```

# Order-Violation Bugs (Cont.)

- **Solution:** Enforce ordering using **condition variables**

```
1  pthread_mutex_t mtLock = PTHREAD_MUTEX_INITIALIZER;
2  pthread_cond_t mtCond = PTHREAD_COND_INITIALIZER;
3  int mtInit = 0;
4
5  Thread 1::
6  void init(){
7      ...
8      mThread = PR_CreateThread(mMain,...);
9
10     // signal that the thread has been created.
11     pthread_mutex_lock(&mtLock);
12     mtInit = 1;
13     pthread_cond_signal(&mtCond);
14     pthread_mutex_unlock(&mtLock);
15     ...
16 }
17
18 Thread2::
19 void mMain(...) {
20     ...
```

# Order-Violation Bugs (Cont.)

```
21      // wait for the thread to be initialized ...
22      pthread_mutex_lock(&mtLock);
23      while(mtInit == 0)
24          pthread_cond_wait(&mtCond, &mtLock);
25      pthread_mutex_unlock(&mtLock);
26
27      mState = mThread->State;
28      ...
29 }
```

# Deadlock Bugs

Thread 1:

`lock(L1);`

`lock(L2);`

Thread 2:

`lock(L2);`

`lock(L1);`

- ◆ The presence of a cycle

- Thread1 is holding a lock L1 and waiting for another one, L2.
- Thread2 that holds lock L2 is waiting for L1 to be release.

# Why Do Deadlocks Occur?

## ▣ Reason 1:

- ◆ In large code bases, **complex dependencies** arise between components.

## ▣ Reason 2:

- ◆ Due to the nature of **encapsulation**
  - Hide details of implementations and make software easier to build in a modular way.
  - Such **modularity** *does not mesh* well with locking.

# Why Do Deadlocks Occur? (Cont.)

## ▣ **Example:** Java Vector class and the method `AddAll()`

```
1    Vector v1,v2;  
2    v1.AddAll(v2);
```

- ◆ **Locks** for both the vector being added to (`v1`) and the parameter (`v2`) *need to be acquired*. Required to have a thread-safe method.
  - The routine acquires said locks in some arbitrary order (`v1` then `v2`).
  - If some other thread calls `v2.AddAll(v1)` at nearly the same time → We have the potential for **deadlock**.

# Conditional for Deadlock

- ▣ Four conditions need to hold for a deadlock to occur.

Condition	Description
Mutual Exclusion	Threads claim exclusive control of resources that they require.
Hold-and-wait	Threads hold resources allocated to them while waiting for additional resources
No preemption	Resources cannot be forcibly removed from threads that are holding them.
Circular wait	There exists a circular chain of threads such that each thread holds one more resources that are being requested by the next thread in the chain

- ◆ If any of these four conditions are not met, **deadlock cannot occur**.

# Prevention – Circular Wait

- ▣ Provide a **total ordering** on lock acquisition
  - ◆ This approach requires *careful design* of global locking strategies.
- ▣ **Example:**
  - ◆ There are two locks in the system (L1 and L2)
  - ◆ We can prevent deadlock by always acquiring L1 before L2.
- ▣ TIP: Acquire the locks in the order of the address

```
1. if (m1 > m2) { // grab locks in high-to-low address order
2.   pthread_mutex_lock(m1);
3.   pthread_mutex_lock(m2);
4. } else {
5.   pthread_mutex_lock(m2);
6.   pthread_mutex_lock(m1); }
7. // Code assumes that m1 != m2 (it is not the same lock)
```

# Prevention – Hold-and-wait

- ▣ Acquire all locks **at once, atomically**.

```
1    lock(prevention);  
2    lock(L1);  
3    lock(L2);  
4    ...  
5    unlock(prevention);
```

- ◆ This code guarantees that **no untimely thread switch can occur** *in the midst of* lock acquisition.
- ◆ **Problem:**
  - Require us to know when calling a routine exactly which locks must be held and to acquire them ahead of time.
  - Decrease *concurrency*

# Prevention – No Preemption

- ❑ **Multiple lock acquisition** often gets us into trouble because when waiting for one lock **we are holding another**.
- ❑ `trylock()`
  - ◆ Used to build a *deadlock-free, ordering-robust* lock acquisition protocol.
  - ◆ Grab the lock (if it is available).
  - ◆ Or, return -1: you should try again later.

```
1  top:
2      lock(L1);
3      if( tryLock(L2) == -1 ){
4          unlock(L1);
5          goto top;
6      }
```

# Prevention – No Preemption (Cont.)

## □ *livelock*

- ◆ Both systems are running through the code sequence *over and over again*.
- ◆ Progress is not being made.
- ◆ Solution:
  - Add a **random delay** before looping back and trying the entire thing over again.

# Prevention – Mutual Exclusion

## □ wait-free

- ◆ Using powerful **hardware instruction**.
- ◆ You can build data structures in a manner that *does not require explicit locking*.

```
1  int CompareAndSwap(int *address, int expected, int new){
2      if(*address == expected){
3          *address = new;
4          return 1; // success
5      }
6      return 0;
7  }
```

# Prevention – Mutual Exclusion (Cont.)

- We now wanted to **atomically increment** a value by a certain amount:

```
1  void AtomicIncrement(int *value, int amount){
2      do{
3          int old = *value;
4      }while( CompareAndSwap(value, old, old+amount)!=0);
5  }
```

- ◆ Repeatedly tries to update the value to *the new amount* and uses the compare-and-swap to do so.
- ◆ **No lock** is acquired
- ◆ **No deadlock** can arise
- ◆ **livelock** is still a possibility.

# Prevention – Mutual Exclusion (Cont.)

## ▣ More complex example: list insertion

```
1  void insert(int value){
2      node_t * n = malloc(sizeof(node_t));
3      assert( n != NULL );
4      n->value = value ;
5      n->next = head;
6      head    = n;
7  }
```

- ◆ If called by multiple threads at the *"same time"*, this code has a **race condition**.

# Prevention – Mutual Exclusion (Cont.)

## ▣ Solution:

- ◆ Surrounding this code with a **lock acquire** and **release**.

```
1  void insert(int value){
2      node_t * n = malloc(sizeof(node_t));
3      assert( n != NULL );
4      n->value = value ;
5      lock(listlock); // begin critical section
6      n->next = head;
7      head    = n;
8      unlock(listlock) ; //end critical section
9  }
```

- ◆ **wait-free manner** using the compare-and-swap instruction

```
1  void insert(int value) {
2      node_t *n = malloc(sizeof(node_t));
3      assert(n != NULL);
4      n->value = value;
5      do {
6          n->next = head;
7      } while (CompareAndSwap(&head, n->next, n));
8  }
```

# Deadlock Avoidance via Scheduling

- ▣ In some scenarios **deadlock avoidance** is preferable.
  - ◆ **Global knowledge** is required:
    - Which locks various threads might grab during their execution.
    - Subsequently schedules said threads in a way as to guarantee no deadlock can occur.

# Example of Deadlock Avoidance via Scheduling (1)

- We have two processors and four threads.

- ◆ Lock acquisition demands of the threads:

	T1	T2	T3	T4
L1	yes	yes	no	no
L2	yes	yes	yes	no

- ◆ A smart scheduler could compute that as long as T1 and T2 are not run at the same time, **no deadlock** could ever arise.

# Example of Deadlock Avoidance via Scheduling (2)

- More contention for the same resources

	T1	T2	T3	T4
L1	yes	yes	yes	no
L2	yes	yes	yes	no

- A possible schedule that guarantees that *no deadlock* could ever occur.

- The total time to complete the jobs is lengthened considerably.
- Little utility (except in upfront know environments, like embedded)

# Detect and Recover

- **Allow deadlock** to occasionally occur and then *take some action*.
  - ◆ **Example:** if an OS froze, you would reboot it.
- Many database systems employ *deadlock detection and recovery technique*.
  - ◆ A deadlock detector **runs periodically**.
  - ◆ Building a **resource graph** and checking it for cycles.
  - ◆ In deadlock, the system **need to be restarted**.
