

# 9: Scheduling: Proportional Share

Operating System: Three Easy Pieces

---

# Proportional Share Scheduler

## ▣ Fair-share scheduler

- ◆ Guarantee that each job obtain *a certain percentage* of CPU time.
- ◆ Not optimized for turnaround or response time

# Basic Concept

## ▣ Tickets

- ◆ Represent the share of a resource that a process should receive
- ◆ The percent of tickets represents its share of the system resource in question.

## ▣ Example

- ◆ There are two processes, A and B.
  - Process A has 75 tickets → receive 75% of the CPU
  - Process B has 25 tickets → receive 25% of the CPU

# Lottery scheduling

- ❑ The scheduler picks a winning ticket.
  - ◆ Load the state of that *winning process* and runs it.

- ❑ Example

- ◆ There are 100 tickets
  - Process A has 75 tickets: 0 ~ 74
  - Process B has 25 tickets: 75 ~ 99

Scheduler's winning tickets: 63 85 70 39 76 17 29 41 36 39 10 99 68 83 63

Resulting scheduler: A B A A B A A A A A A B A B A

**The longer these two jobs compete,  
The more likely they are to achieve the desired percentages.**

# Ticket Mechanisms

## ▣ Ticket currency

- ◆ A user allocates tickets among their own jobs in whatever currency they would like.
- ◆ The system converts the currency into the correct global value.
- ◆ Example
  - There are 200 tickets (Global currency)
  - Process A has 100 tickets
  - Process B has 100 tickets

**User A**     $\rightarrow 500$  (A's currency) to A1  $\rightarrow 50$  (global currency)  
              $\rightarrow 500$  (A's currency) to A2  $\rightarrow 50$  (global currency)

**User B**     $\rightarrow 10$  (B's currency) to B1  $\rightarrow 100$  (global currency)

# Ticket Mechanisms (Cont.)

## ▣ Ticket transfer

- ◆ A process can temporarily hand off *its tickets* to another process.

## ▣ Ticket inflation

- ◆ A process can temporarily raise or lower the number of tickets it owns.
- ◆ If any one process needs *more CPU time*, it can boost its tickets.

# Implementation

- Example: There are three processes, A, B, and C.
  - Keep the processes in a list:

```
1 // counter: used to track if we've found the winner yet
2 int counter = 0;
3
4 // winner: use some call to a random number generator to
5 // get a value, between 0 and the total # of tickets
6 int winner = getrandom(0, totaltickets);
7
8 // current: use this to walk through the list of jobs
9 node_t *current = head;
10
11 // loop until the sum of ticket values is > the winner
12 while (current) {
13     counter = counter + current->tickets;
14     if (counter > winner)
15         break; // found the winner
16     current = current->next;
17 }
18 // 'current' is the winner: schedule it...
```

# Implementation (Cont.)

- ▣  $U$ : unfairness metric

- ◆ The time the first job completes divided by the time that the second job completes.

- ▣ Example:

- ◆ There are two jobs, each jobs has runtime 10.
  - First job finishes at time 10
  - Second job finishes at time 20
- ◆  $U = \frac{10}{20} = 0.5$
- ◆  $U$  will be close to 1 when both jobs finish at nearly the same time.

# Lottery Fairness Study

- ▣ There are two jobs.
  - ◆ Each jobs has the same number of tickets (100).

**When the job length is not very long,  
average unfairness can be quite severe.**

# Stride Scheduling

## ▣ Stride of each process

- ◆ (A large number) / (the number of tickets of the process)
- ◆ Example: A large number = 10,000
  - Process A has 100 tickets → stride of A is 100
  - Process B has 50 tickets → stride of B is 200

- ## ▣ A process runs, increment a counter(=pass value) for it by its stride.
- ◆ Pick the process to run that has the lowest pass value

```
current = remove_min(queue);           // pick client with minimum pass
schedule(current);                     // use resource for quantum
current->pass += current->stride;        // compute next pass using stride
insert(queue, current);                 // put back into the queue
```

**A pseudo code implementation**

# Stride Scheduling Example

| Pass(A)<br>(stride=100) | Pass(B)<br>(stride=200) | Pass(C)<br>(stride=40) | Who Runs? |
|-------------------------|-------------------------|------------------------|-----------|
| 0                       | 0                       | 0                      | A         |
| 100                     | 0                       | 0                      | B         |
| 100                     | 200                     | 0                      | C         |
| 100                     | 200                     | 40                     | C         |
| 100                     | 200                     | 80                     | C         |
| 100                     | 200                     | 120                    | A         |
| 200                     | 200                     | 120                    | C         |
| 200                     | 200                     | 160                    | C         |
| 200                     | 200                     | 200                    | ...       |

If new job enters with pass value 0,  
It will **monopolize** the CPU!
