9: Scheduling: Proportional Share

Operating System: Three Easy Pieces

Proportional Share Scheduler

- Fair-share scheduler
 - Guarantee that each job obtain a certain percentage of CPU time.
 - Not optimized for turnaround or response time

Basic Concept

Tickets

- Represent the share of a resource that a process should receive
- The percent of tickets represents its share of the system resource in question.

Example

- There are two processes, A and B.
 - Process A has 75 tickets → receive 75% of the CPU
 - Process B has 25 tickets → receive 25% of the CPU

Lottery scheduling

- □ The scheduler picks <u>a winning ticket</u>.
 - Load the state of that winning process and runs it.
- Example
 - There are 100 tickets
 - Process A has 75 tickets: 0 ~ 74
 - Process B has 25 tickets: 75 ~ 99

Scheduler's winning tickets: 63 85 70 39 76 17 29 41 36 39 10 99 68 83 63

Resulting scheduler: A B A A B A A A A B A B A

The longer these two jobs compete,
The more likely they are to achieve the desired percentages.

Ticket Mechanisms

Ticket currency

- A user allocates tickets among their own jobs in whatever currency they would like.
- The system converts the currency into the correct global value.
- Example
 - There are 200 tickets (Global currency)
 - Process A has 100 tickets
 - Process B has 100 tickets

```
User A \rightarrow 500 (A's currency) to A1 \rightarrow 50 (global currency)

\rightarrow 500 (A's currency) to A2 \rightarrow 50 (global currency)

User B \rightarrow 10 (B's currency) to B1 \rightarrow 100 (global currency)
```

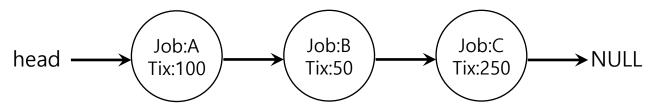

Ticket Mechanisms (Cont.)

- Ticket transfer
 - A process can temporarily <u>hand off</u> its tickets to another process.

- Ticket inflation
 - A process can temporarily raise or lower the number of tickets is owns.
 - If any one process needs *more CPU time*, it can boost its tickets.

Implementation

- Example: There are there processes, A, B, and C.
 - Keep the processes in a list:

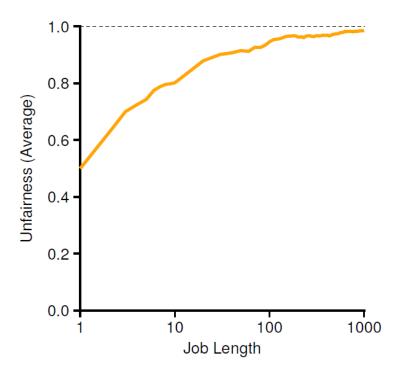

```
// counter: used to track if we've found the winner yet
1
          int counter = 0;
3
          // winner: use some call to a random number generator to
5
          // get a value, between 0 and the total # of tickets
6
          int winner = getrandom(0, totaltickets);
          // current: use this to walk through the list of jobs
          node t *current = head;
9
10
          // loop until the sum of ticket values is > the winner
11
12
          while (current) {
13
                    counter = counter + current->tickets;
14
                    if (counter > winner)
15
                              break; // found the winner
16
                    current = current->next;
17
          // 'current' is the winner: schedule it...
18
```

Implementation (Cont.)

- □ U: unfairness metric
 - The time the first job completes divided by the time that the second job completes.
- Example:
 - There are two jobs, each jobs has runtime 10.
 - First job finishes at time 10
 - Second job finishes at time 20
 - $U = \frac{10}{20} = 0.5$
 - U will be close to 1 when both jobs finish at nearly the same time.

Lottery Fairness Study

- There are two jobs.
 - Each jobs has the same number of tickets (100).

When the job length is not very long, average unfairness can be quite severe.

Stride Scheduling

- Stride of each process
 - (A large number) / (the number of tickets of the process)
 - Example: A large number = 10,000
 - Process A has 100 tickets → stride of A is 100
 - Process B has 50 tickets → stride of B is 200

- A process runs, increment a counter(=pass value) for it by its stride.
 - Pick the process to run that has the lowest pass value

A pseudo code implementation

Stride Scheduling Example

Pass(A) (stride=100)	Pass(B) (stride=200)	Pass(C) (stride=40)	Who Runs?
0	0	0	Α
100	0	0	В
100	200	0	C
100	200	40	C
100	200	80	C
100	200	120	Α
200	200	120	C
200	200	160	C
200	200	200	•••

If new job enters with pass value 0, It will monopolize the CPU!
