26. Concurrency: An Introduction

Operating System: Three Easy Pieces

Thread

A new abstraction for a single running process

- Multi-threaded program
 - A multi-threaded program has more than one point of execution.
 - Multiple PCs (Program Counter)
 - They share the same address space.

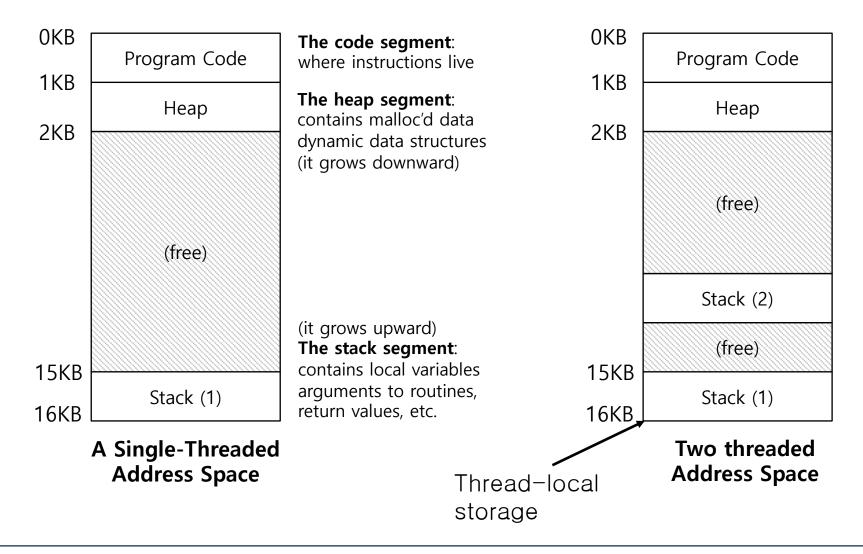

Context switch between threads

- Each thread has its own <u>program counter</u> and <u>set of registers</u>.
 - One or more thread control blocks(TCBs) are needed to store the state
 of each thread.
 - All of then within a common PCB

- \blacksquare When switching from running one (T1) to running the other (T2),
 - The register state of T1 be saved.
 - The register state of T2 restored.
 - The address space remains the same.

The stack of the relevant thread

There will be one stack per thread.

Why threads?

Performance

- Parallelism is the only way to use translate multiple cores into performance
- Parallelization: from single-threaded programs to multi-threaded

Convenience

• Way to overlap I/O with useful work: approach of server-base applications such as web-servers, DBMS, etc..

```
#include <stdio.h>
1
    #include <assert.h>
    #include <pthread.h>
4
    void *mythread(void *arg) {
        printf("%s\n", (char *) arg);
6
        return NULL;
7
8
9
    int
10
    main(int argc, char *argv[]) {
11
        pthread_t p1, p2;
12
        int rc;
13
        printf("main: begin\n");
14
        rc = pthread_create(&p1, NULL, mythread, "A"); assert(rc == 0);
15
        rc = pthread_create(&p2, NULL, mythread, "B"); assert(rc == 0);
16
        // join waits for the threads to finish
17
        rc = pthread_join(p1, NULL); assert(rc == 0);
18
        rc = pthread_join(p2, NULL); assert(rc == 0);
19
        printf("main: end\n");
20
        return 0;
21
22
```

Figure 26.2: Simple Thread Creation Code (t0.c)

Possible outcomes

main	Thread 1	Thread2	main		Thread 1	Thread2
starts running prints "main: begin" creates Thread 1	rints "main: begin"		starts running prints "main: begin" creates Thread 1			
creates Thread 2 waits for T1	runs				runs prints "A" returns	
L. C. TO	prints "A" returns		creates Thread	2		runs prints "B"
waits for T2		runs prints "B"	waits for T1 returns immediately; T1 is done waits for T2			returns
prints "main: end"		returns	returns immediately; T2 is done prints "main: end"			
	_ mai	in	Thread 1	Thread2		
	prir crea	rts running nts "main: begin" ntes Thread 1 ntes Thread 2				
		1- (T1		runs prints "B" returns		
	waits for T1		runs prints "A" returns			
	ret	ts for T2 turns immediately; T2 is done nts "main: end"				

```
#include <stdio.h>
    #include <pthread.h>
    #include "mythreads.h"
    static volatile int counter = 0;
    //
   // mythread()
   //
   // Simply adds 1 to counter repeatedly, in a loop
   // No, this is not how you would add 10,000,000 to
   // a counter, but it shows the problem nicely.
   //
13
   void *
14
   mythread(void *arg)
15
16
17
        printf("%s: begin\n", (char *) arg);
18
        int i;
        for (i = 0; i < 1e7; i++) {
19
20
            counter = counter + 1;
21
22
        printf("%s: done\n", (char *) arg);
23
        return NULL;
24
25
    //
26
   // main()
   //
28
   // Just launches two threads (pthread_create)
    // and then waits for them (pthread_join)
    //
31
   int
    main(int argc, char *argv[])
34
35
        pthread_t p1, p2;
36
        printf("main: begin (counter = %d)\n", counter);
        Pthread_create(&p1, NULL, mythread, "A");
37
        Pthread_create(&p2, NULL, mythread, "B");
38
39
40
        // join waits for the threads to finish
        Pthread_join(p1, NULL);
41
42
        Pthread_join(p2, NULL);
        printf("main: done with both (counter = %d)\n", counter);
43
44
        return 0;
```

Possible outcomes

```
prompt> gcc -o main main.c -Wall -pthread
prompt> ./main
main: begin (counter = 0)
A: begin
B: begin
A: done
B: done
main: done with both (counter = 20000000)
```

```
prompt> ./main
main: begin (counter = 0)
A: begin
B: begin
A: done
B: done
main: done with both (counter = 19345221)
```

```
prompt> ./main
main: begin (counter = 0)
A: begin
B: begin
A: done
B: done
main: done with both (counter = 19221041)
```

The heart of the problem: : Uncontrolled Scheduling

Example with two threads

- counter = counter + 1 (default is 50)
- We expect the result is 52. However,

			(after instruction)		
OS	Thread1	Thread2	PC	%eax	counter
	before critical section			0	50
	mov 0x8049a	alc, %eax	105	50	50
	add \$0x1, 8	eax	108	51	50
interrupt save T1's state restore T2's sta	te	mov 0x8049a1c, %eax add \$0x1, %eax mov %eax, 0x8049a1c	100 105 108 113	0 50 51 51	50 50 50 51
interrupt save T2's state					
restore T1's sta	te		108	51	50
	mov %eax, 0	0x8049a1c	113	51	51

The wish for atomicity

- Do the read and modification of the memory in a single step
 - i.e. "all or nothing"!

- How ho handle complex data? (v.gr. a b-tree)
 - Use some atomic hardware support (called synchronization primitives) to construct OS support

- A piece of code that accesses a shared variable and must not be concurrently executed by more than one thread.
 - Multiple threads executing critical section can result in a race condition.
 - Need to support atomicity for critical sections (mutual exclusion)

Locks

Ensure that any such critical section executes as if it were a single atomic instruction (execute a series of instructions atomically).

```
1  lock_t mutex;
2  . . .
3  lock(&mutex);
4  balance = balance + 1;
5  unlock(&mutex);
Critical section
```
